Excerpt: . . . a cathode measuring 3 ins. x 2 ins. , cr a surface exposure of 12 sq. ins. The current used in both the silver and the lead voltameter for these experiments was about 10 amperes per sq. ft. All the deposits of lead formed in all the experiments, except No. 8 and No. 13, were smooth, dense, coherent and non-crystalline. The deposits were not dissolved from the cathodes, but were formed one on top of the other. It might be mentioned that the reason for being so particular about purifying the electrolyte previous to the experiments, and for using such pure lead for the anodes was so as to be certain that any variation in the results would not be due to the impurities. Ordinarily, such care need not be exercised in securing such pure lead for the anodes. A good quality of refined lead is sufficiently pure for general purposes. Conclusions. The better form of voltameter is one with two anodes and one cathode. Suspend the cathode between the two anodes and below the surface of the electrolyte by means of a thin narrow strip of metal or wire, so as to prevent the action of the atmosphere on the lead at the surface of the electrolyte. This action may also be retarded by using an electrolyte which is less acid than that used in the experiments. Even with an almost neutral solution of lead fluo-silicate its conductivity would be sufficiently high for...
